

THE PROTOZOAN PLANKTON AND THEIR SAPROBITY RELATIONS IN THE MAROS (MUREŞ) RIVER

MAGDOLNA CS. BERECZKY

Introduction

Protozoa are without doubt of great importance for both the natural living system and human activity. Their significance regarding the latter cannot be restricted only to the medical and/or veterinary aspects, as their role in the process of self purification or their use as indicator organisms is just as important.

The aims of our investigations were to determine the species composition, abundance relations of planktonic protozoan communities, and to follow the changes of the saprobity relations of the Maros River from its source to the mouth. This investigation was the very first for protozoological research.

Materials and Methods

Water samples were collected from 15 sampling sites along the Maros River. Each time 30 l water was filtered through a net of 10 mesh size. The method used for protozoa is the bromphenol blue test, applied to estimate the protozoa density in planktonic and periphytic communities (Bereczky 1985). In this technique the fresh sample is fixed in HgCl₂ solution and "stained" with bromphenol blue. This method allows an accurate counting of individuals in natural samples. We used Protargol impregnation (modified by Wilbert 1974), as well. Evaluation of saprobity by Foissner (1992).

Discussion

Though we looked through many protozoological works we did not find any previous protozoological investigations of the Maros. This was the reason why at first we wanted to get to know what kind of heterotrophic protists live in this river. We found 148 protozoa species from the source to the mouth:

Amoeba: 9

Testacea: 25

Heliozoa: 22

Ciliata: 92

Ciliata appeared to be the richest community. They are dominant according to both their species number and individual number. Regarding the species diversity and distribution three areas can be distinguished along the river.

The first section is between Izvorul Mureş (source) and Sărmaş (62 km), where the species number was low-average and the individual number was in accordance with flow velocity (see Table 1-4).

From Rastoliţa (105 km) through Tîrgu Mureş (188 riv km, retained water) to Gura Arieşului (282 riv km) extends the region which we identified as the middle section. In this area at Ungheni-Moreşti (207 km) we found the highest species number (39). This community - rich in species - is characteristic of eutrophic waters. In running waters, current rate is one of the most effective factors selecting distribution. In this section, because of the retained water, the river slows and thus the euplanktonic organisms multiply. At site 7 we found *Trachelophyllum clavatum* (Stokes Cl- ion 33.7 mg/l), which is of small density, but is a good indicator organism for salt water occurrence (Table 7).

At Gura Arieşului (below Arieş) the individual number decreases, which may refer to changes in the nearly natural conditions. A drastic anthropogenic environmental effect occurs at Sântimbru (355 km), proved by conductivity of 1117 s/cm and the total lack of protozoan communities. We could not identify even a single representative of the investigated groups (Amoeba, Testacea, Ciliata), only a few empty testacean shells and some ciliata cysts indicate the rich community mentioned above.

The third section of the river begins at Alba Iulia (376 km). The low species number and the high individual number is characteristic of mesosaprobic waters. That is without question. Only 8 species form the community where *Phascolodon vorticella* is dominant and this indicates advanced eutrophication.

The great masses of algae and at the same place the Protozoa become competitors and at this stage (mainly at 375, 445 and 520 km) the autotrophs push the heterotrophs out of the plankton. Under such conditions the afore-mentioned *Phascolodon vorticella* became absolutely dominant with $1359 \cdot 10^3$ ind/m³.

At Deva (455 riv km) the abundance of Protozoa increases and the community is invariably formed of euplanktonic organisms (Table 12).

At Zam (520 km) the individual number begins to decrease, later on at Pecica (676 km) and over Szeged (766 km) come into force such conditions which are characteristic of rivers of the same order (Table 13,14,15).

Most of the Protozoan species found in the Maros as indicators have unknown saprobial classification. The plankto-seston of the upper section is formed by many rare species and is similarly formed by the potamoplankton of the middle and lower sections.

Most species of known saprobity are oligo-beta, betamesosaprobic ones. Though we found alpha- and polysaprobic organisms several times downwards over Rastoliţa, their abundance, though essential to determine indicator values, never reached more than 20% of any community. We found a greater polysaprobic population of *Vorticella microstoma* only below Arieş (282 km).

The saprobic indexes can be found as percentages in Table 16, they are characteristic of water in summers with high temperatures. In this period the elimination of dissolvable organic matters needs shorter time than in winter. Probably, in colder seasons we could find species which indicate much worse water quality.

Introducing the protozoan community according to their nutrition types helps the evaluation of trophy. It can be read from Table 17, that we found mainly algivorous,

algibacteriavorous and bacteriavorous organisms. Detritus- and bacteriavorous species, predators, omnivores and ectocommensalists are relatively few.

At 207 km, and below Arieş we found species in a relatively high percentage of unknown nutrition types. At Alba Iulia the algivorous dominance of 94.5% indicates a change of conditions from eutrophy to hypertrophy. Algivorous species are dominant at Szeged, too.

Summary

In the Maros River there exists a rich protozoan community which would be worth investigating systematically. I found many organisms, which I could identify only to species. This means that it would be possible to find new species for science with the help of quick examinations. I have to mention that the perishing of protozoa at Sântimbru may indicate the beginning of more significant, irreversible environmental damage.

At numerous places I found amoeba belonging to the *Naegleria* genus, which can be identified to species only in laboratory cultures. Some stock of these amoeba has been stated pathogenic. It would be worth extending the investigations to this direction, too.
